Development v. release

- Use assert during the development process
 - to detect (and correct) bugs as early as possible
 - to ease and fast the process
- In release process
 - a program should be robust does not stop if a problem arises
 - so handling errors is not the assert-way
 - so you have to write specific code for that

Development v. release

Handling errors correctly means

- recover a coherent and stable execution state
- having some transversal code in programs it is an "aspect" of your program

Development v. release

About C-like error handling:

- the client has to test procedure return values and usually forget to do so
- when an error is detected, you have to code the "unstacking" (procedure calls) process to get where the error has to be processed...
- that is tedious...

A simple illustration in C

without error management:

```
void baz() {
 // ...
 // an error happens here
 // ...
void bar() {
 // ...
 baz();
 // ...
void foo() {
 // ...
 bar(); // erroneous result...
 //
```

with error management:

```
int baz() {
 // ...
  if (test)
   return -1; // err detected!
 // ...
int bar() {
  // ...
  if (baz() == -1)
    return -1; // unstacking...
  // ...
void foo() {
  // ...
 if (bar() == -1) {
   // err handling...
     ◆ロ → ← 御 → ← 連 → ・ 連 ・ 夕 へ ○
```

Definitions

- An exception is an object that represents the error.
- Such object lives till the error has been properly processed.
- A routine that detects an error throws an exception in the previous example, it is the case for baz
- A routine in which an error might occur can catch this error to do something about it
 - in the previous example, it is surely the case of foo but also the same for bar

- Exceptions
 - Introduction
 - Syntax
 - A "real" class as an exception
- About constructors et al.
 - C++ is like C
 - C++ idioms
 - C++ is just like C: dangerous!
- 3 Live C++ tour

Error hierarchies

An exception is an object so you (as client) can define classes to describe errors:

```
namespace error
{
  class any {};
  class math : public any {}; // abstract class

  // concrete classes
  class overflow : public math {};
  class zero_divide : public math {};
}
```

A error::zero divide is-an error::math.

Throwing an exception

```
float div(float x, float y)
{
    // code for handling err in dev mode:
    assert(y != 0);

    // code for handling err in release mode:
    if (y == 0)
        throw error::zero_divide(); // call to a ctor

    // code when everything is OK
    return x / y;
}
```

Sample behavior

Imagine that program:

```
void baz() {
  // code 3
  div(a, b); // here!
  // code 4
void bar() {
  // code 2
  baz();
  // code 5
void foo() { // called somewhere
  // code 1
  bar(); // if not OK, continue
  // code 6
```

If b != 0 in baz, execution performs:

- first code 1 to code 3,
- then div(a,b) that works fine,
- last code 4 to code 6.

If b == 0, execution should perform

- first code 1 to code 3,
- div(a,b) that does not work,
- then some specific code to handle this error!
- and last code 6 (program resumes)

Handling error

With error handling code in "foo":

```
void baz() {
   // code 3
   div(a, b); // can fail!
   // code 4
}

void bar() {
   // code 2
   baz();
   // code 5
}
```

If no error occurs:

```
code \ 1 \rightarrow code \ 2 \rightarrow code \ 3 \rightarrow div \rightarrow code \ 4 \rightarrow code \ 5 \rightarrow code \ 6
```

If an error occurs:

```
code \ 1 \rightarrow code \ 2 \rightarrow code \ 3 \rightarrow div \rightarrow err \ msg
```

Recovery from error

```
void bar()
  data* ptr = 0;
  trv {
    // ...
    baz();
    // ...
    ptr = new data; // dyn alloc
    // ...
    baz();
    // ...
  catch (...) {
    if (ptr)
      delete ptr;
    throw;
```

- the 2nd call to baz might fail
- in this example, some action is performed before this call (ptr allocation)
- bar has to perform some recovery code if an error occurs during that call (ptr deallocation)
- the catch code block is run when an exception has been thrown
- error handling is not completed so the caught exception is thrown again (instruction throw;); the error is still alive...

Handling error (2/2)

With a more complete error handling code:

```
void baz() {
 trv {
    // code 3
                                   void foo()
    div(a, b); // can fail!
    // code 4
                                      trv {
                                       // code 1
  // code Z: catch, fix, and throw
                                       bar();
                                        // code 6
void bar() {
                                      catch (...) {
 trv {
                                        // "..." means "any exception"
    // code 2
                                        std::cerr << "bar aborted!"
    baz();
                                                  << std::endl;
    // code 5
  // code R: catch, fix, and throw
```

If an error occurs:

 $\mathsf{code}\ 1 \to \mathsf{code}\ 2 \to \mathsf{code}\ 3 \to \mathsf{div} \to \mathsf{code}\ Z \to \mathsf{code}\ R \to \mathsf{err}\ \mathsf{msg}_{\mathbb{P}} \ \mathsf{loc}\ \mathbb{P} \ \mathsf{loc}\ \mathbb{P} \ \mathsf{loc} \ \mathbb{P} \ \mathsf{loc}\ \mathsf{loc$

Selecting errors to handle

```
void foo() {
  try {
    // ...
  catch (error::zero divide) {
    // handles such error
  catch (error::math) {
                                        catch clauses are inspected in the
    // handles other math errors
                                          order they are listed
                                        the appropriate catch clause is
  catch (error::any) {
                                          selected from the error type
    // handles non-math client errors
                                          the corresponding code is run
  catch (std::bad alloc) {
    // handles an allocation ('new') that failed
  catch (...) {
    // handles all remaining kinds of errors
```

- Exceptions
 - Introduction
 - Syntax
 - A "real" class as an exception
- 2 About constructors et al.
 - C++ is like C
 - C++ idioms
 - C++ is just like C: dangerous!
- 3 Live C++ tour

The "real" class

```
namespace error
           class problem : public any
           public :
                       problem(const std::string& filename,
                                                                       unsigned line.
                                                                       const std::string& msg);
                      unsigned line() const;
                      // ...
                                                                                                                                                                                                            std::ostream&
           private:
                                                                                                                                                                                                            operator << (std::ostream& ostr,
                       std::string filename ;
                                                                                                                                                                                                                                                                              const error::problem& pb)
                      unsigned line_;
                       std::string msg_;
                                                                                                                                                                                                                       ostr << "err in " << pb.filename()
            };
                                                                                                                                                                                                                                                      << "at line " << pb.line()
                                                                                                                                                                                                                                                      << ": " << pb.msq();
                                                                                                                                                                                                                       return ostr;
                                                                                                                                                                                                                                                                                                  <ロ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □ > ← □
```

Using the exception object

An exception is thrown an object is constructed

The exception is caught the object is inspected

```
void compile() {
   try {
      // parse something...
  }
   catch(error::problem& pb) {
      std:cerr << pb << std::endl;
      // pb is a regular object!
   }
}.</pre>
```

- 1 Exception
 - Introduction
 - Syntax
 - A "real" class as an exception
- About constructors et al.
 - C++ is like C
 - C++ idioms
 - C++ is just like C: dangerous!
- 3 Live C++ tour

C behavior (1/3)

```
struct foo
 int i;
 float* ptr;
};
int main()
 foo* C = malloc(sizeof(foo));
 foo a, aa; // constructions
  foo b = a; // copy construction
 // but:
  aa = a; // assignment
} // a, aa, and b die
  // C also dies (niark!)
  // so who does not?
```

```
void bar (foo d)
 // ...
} // d dies
foo baz()
 foo e;
 // ...
 return e; // e is copied
            // while baz returns
} // e dies
int main()
 foo f; // construction
  bar(f); // d is copied from f
           // when bar is called
} // f dies
```

C behavior (2/3)

with:

```
struct foo { int i; float* ptr; };
int main() {
  foo* C = malloc(sizeof(foo));
  foo a, aa; // constructions
  foo b = a; // copy construction
  aa = a; // assignment
}
```

we have:

expression	value
C->i and C->ptr	undefined
a.i and a.ptr	undefined
b.i and b.ptr	resp. equal to a.i and a.ptr
aa.i and aa.ptr	likewise

C behavior (3/3)

```
foo::foo() :
this C code:
                                 b() // calls bar::bar()
                               {} // to construct this->b
struct bar {/*...*/};
                               foo::foo(const foo& rhs) :
                                 b(rhs.b), // calls bar::bar(const bar&
struct foo {
                                           // to cpy construct this->b
 bar b; int i; float* ptr;
                                 i(rhs.i), // integer cpy
};
                                 ptr(rhs.ptr) // pointer cpy
is equivalent to the C++
                               {}
code:
                               foo& foo::operator=(const foo& rhs) {
                                 if (&rhs == this) return *this;
class foo {
                                 this->b = rhs.b;
public:
                                 this->i = rhs.i;
 foo();
                                 this->ptr = rhs.ptr;
 foo(const foo& rhs);
 foo& operator=(const foo& rhs),; return *this;
  ~foo();
public: // no hiding!
                               foo:: ~foo()
  bar b; int i; float* ptr;
                               {} // automatically calls bar:: bar()
};
                                  // on this->b so this >b dies = ogo
```

- Exceptions

- 3 Live C++ tour

C++ special methods

```
return_t type::method(/* some args */) a regular method

special methods:

type::type() constructor without argument

type::type(const type&) copy constructor

type& type::operator=(const type&) assignment operator

type::~type() destructor

(and then you die)
```

when the programmer does not code one of these special methods, the compiler (in most cases...) adds this method following the C behavior.

Special methods and inheritance

```
class base // are belong to us
public:
 base();
 base(int b):
 base (const base& rhs);
  base& operator=(const base& rhs);
 virtual ~base();
protected:
 int b ; /*...*/
};
class derived : public base
public:
 derived():
 derived (int b, float d);
  derived(const derived& rhs);
  derived& operator=(const derived& rhs);
  ~derived():
private:
  float d : //...
};
```

```
derived::derived() :
  base(), d (0) //...
// allocate resource when needed
derived::derived(int b, float d) :
  base(b /*...*/), d (d) //...
 // allocate resource when needed
derived::derived(const derived& rhs) :
  base(rhs), d (rhs.d ) //...
 // allocate resource when needed
derived& derived::operator=(const derived& rhs)
  if (&rhs == this)
     return *this:
  this->base::operator=(rhs);
  this->d = rhs.d; //...
  return *this:
derived:: "derived()
{ // resource deallocation when needed
  // warning: do NOT call base:: "base()
```

Comments

- please strictly follow the idioms given in the previous slide
- this->b_, as an attribute of base, is not processed in special methods of derived
- each constructor of derived first calls the appropriate constructor of base
- in the destructor body (there is one per class), do not call the destructor of base classes
- in constructors and destructor bodies, do not call on this any virtual method from the same hierarchy

 - Introduction
 - Syntax
 - A "real" class as an exception
- About constructors et al.
 - C++ is like C
 - C++ idioms
 - C++ is just like C: dangerous!
- 3 Live C++ tour

what's the problem?

```
class easy
public:
  easy();
                                 void naive (easy bug)
  ~easv();
private:
                                   // nothing done so ok!
  float* ptr :
};
                                 int main()
easy::easy()
{ // allocate a resource so...
                                   easy run;
  this->ptr_ = new float;
                                   naive (run);
easy::~easy()
                                 // compile but fail at run-time!!!
{ // ...deallocate it!
  delete this->ptr_;
  this->ptr_ = 0; // really a safety!
```

a soluce

```
either:
                                 or:
class easy
                                 class easy
                                 public:
public:
  easv(); // defined in .cc
                                   // defined in .cc
  ~easy(); // defined in .cc
                                   easy();
                                   ~easv();
                                   easy(const easy& rhs);
  // declared only:
  easy(const easy&);
                                   easy& operator=(const easy& rhs);
                                   // and with great care!
 void operator=(const easy&);
  // so NOT defined in .cc
                                 private:
private:
                                   float* ptr ;
                                 };
  float* ptr_;
};
```

Objectives

- classes
 - \Rightarrow encapsulation (attributes + methods) and information hiding
- a class hierarchy
 - ⇒ inheritance with an abstract class and concrete sub-classes
- special methods (ctors, cpy ctor, dtor, op=)
- design of class interfaces
- use of std:: tools:
 - output stream
 - a container
 - iterations
- everything in a namespace

Needs

- several kinds of shapes
- a shape is in a page
- a page can be copied; a shape can be cloned
- every objects are printable
- an exception arises when calling circle::r_set (-1)

Now code

- - -
